# notes on the porcupines of the malay peninsula AND ARCHIPELAGO. 

By Marcus Ward Lyon, Jr.,
Assistant Curator, Division Mammals, L. S. National Muspum

The following notes are of a preliminary nature only, and are written with the idea of bringing together in one place a consideration of the sristematic names of the Malayan porcupines and the characters by which these animals are arranged into natural groups, both of which considerations are at present scattered through various publications. The main features brought out in this paper are the division of the Old World poreupines into two subfamilies; the revival of Cuvier's name Acanthion as a genus for the short-tailed Malayan poreupines; the revival of Limmens name Mystri, brachymu as the proper specitic designation of the short-tailed porcupine of the Malay Peninsulat; the description of a new gents and species of short-tailed porcupine collected in northern Sumatra by Dr. W. L. Abhott in 1906; and the description of a new species of Itherrmes from Pulo Terutau, off the west coast of the Malay Peninsula. The presence of two distinct gencra of long-tailed porcupines in the Malayan region eaused considerable confusion in the use of names by the older writers, but Jentink. ${ }^{\text {I }}$ in $159 t$, clearly pointed out the true status of these groups. Seba was well acquainted with three of the four genera of Old World poreupines that have been recognized up to the present time, and it was largely from his deseriptions and plates that Limmens in the tenth edition of the Systema Naturae based three names of the OId Workd porcupines, which at that time were regarded as so many distinct species and not as distinct generic types as they have since been considered.

It is to regretted that more examples of the typical genus Mystrix have not been available in the preparation of these notes for determining the true status of the gemus, Icanthion, which has nsually been

[^0]considered synonymous with part of Iystri.r. However, the material at hand shows very considerable differences between IHstrix proper and Acunthion, which will be pointed out further on. With regard to some of the species in the various genera of Malayan porcupines, I have not seen a sufficient number of specimens to determine the characters satisfactorily. Where several forms of one group, each form occupying a detinite and isolated geographic area, have been named I have made use of the names bestowed upon them even if their specific characters are not clear, believing this plan better than to place them under one specific name, for material is as lacking to show their identity as it is to show their distinctness.

The list of works to which reference has been made in preparing these notes will be found under the synonymy of the different species or referred to in footnotes. The specimens on which these notes are based are listed in the table of measurements, page 593. They represent forty individuals from Malaya, thirty-three skins with skulls, two odd skulls, and five skeietons. All but three of these specimens were collected by Dr. W. L. Abbott, and have been presented by him to the U. S. National Museum.

## key to the genera of malayan porcupines.

a Tail short, less than one-fourth length of head and borly; caudal hairs terminating mostly in hollow capsule-like structures, molars rootless, sacral vertebre four Subfamily Hystricine, p. 578
$b$ Dorsal profile of skull arched, nasals extending back to level of lachrymals, and contained into dorsal outline two and one-half times......... Acanthion, p. 578
$b b$ Dorsal profile of skull nearly straight, nasals extending back to level of anterior border of infraorbital foramen, contained into dorsal outline three and onehalf times.................................................................. . Thecurus, p. 582
au Tail long, one-third to one-half length of head and body, terminating in a tuft of morlified bristles, molars rooted, sacral vertebree three.

Subfamily Atherurin.e, p. 584
c Each caudal scale subtended by three hairs, terminal bristles alternately expanded and contracted . ......................................... Atherurus, p. 584 cc Each caudal scale subtended by a single hair, terminal bristles of uniform width throughout.............................................................. Thys, p. 588

Tabular view of the principal external and cranial characters of the genera of Old World porcupines.

Tubutar view of the principal eaternal and cramial characters of the genera of Old World porcupines-Continued.

## C'haracters.

A mane or crest of long bristles on nape and upper back
Nape and upper back mainly covered with flattened, grooved spines.
Long quills ( 150 to 300 mm .), dark, with light rings, on lower back
Long quills ( 130 mm .) , dark, with light base and apex and grooved flattenerd spines on lower back
No quills in pelage, all grooved flattened spines, a few long stiff bristles on lower back

Witth of a single nasal contained in its length less than three times.
Width of a single nasal contained in its length about four times
Nasals extend backward on upper sarface of skull as far baek as squamosal roots of zygomata, contained in doral outline one and one-half times
Nasals mainly confined to rostrum, back omly to level of lachrymal, contained into lorsal ontline two and one-half times.
Nasals contined to rostrum, back to anterior margin of infraorbital foramen contained into dorsal outline three and one-half times.

Malar thin but relatively very broad, without groove on lateral faee
Nalar thick but relatively narrow, with well-marked groove on lateral face.
Inferior bar of infraorbital foramen slender
Inferior bar of infraorbital foramen heavy
Outer bar of infraorbital foramen heary
Outer bar of infraorbital foramen slender
Zygomatie process of maxilla forming only a very slight support for malar
Zygomatic process of maxilla forming a well-marked backward suphort for matar

No interorbital constriction
Interorbital constriction slightly indicated
Evident, but slight interorbital constriction
Well-marked interorbital eonstriction
A depresion on top of skull at meeting of sagittal and coronal sutures at a level poxterior to squamosal roots of zygomata
No depression on top of skull at meeting of sagittal and coronal sutures which meet on line with squamosal roots of zygomata.

Supero-posterior lateral aspeet of maxilla angular
supero-posterior lateral aspect of maxilla rounded
Basi-nccipito-sphenoid searcely narrowed between perygoids
Basi-oceipito-s ohenoid much narrowed between pterygoids.
Well-marked fossa on outside of mandible just beneath cendylo-coronoid notch No well-marked fossa on outside of mandible just beneath condylo-coronoid notch.

Number of dorsal vertebre
Number of Lumbar vertebrea
Number of sacral vertebrea

[^1]subfanily HYs'IRICIN F.

The subfamily Hystricina is characterized among the Hystricide by having a short external tail, without a well-marked hairless scaly portion between its hase and apex, in having the terminal hairs of the tail modified into hollow eapsule-like structures, mostly open at the ends, in the possession of well-developed quills on the back, in having four sacral vertebra, and rootless, hypsidont molars. It contains three genera: Ifystrix (not considered in these notes, because not found in the Malayan subregion), Acanthion, page 578, and Thecurus, page $58 \%$.

## ACANTHION F. Cuvier.

1822. Arenthim F. Cuvier, Mem. Mus. Hist. Nat. Paris, LX, 1822, p. 413, pl. xx his, figs. $3,4$.
Type.-Acanthion jaranictm, from Java.
Specier.-Acunthion bruchyurum (Linnens), Malay Peninsula; A. longicoudum (Marsden). Sumatra; A. jaranicum F. Cuvier, Java; A. crassispinis (Günther), Borneo.

Diegmostic characters.-Externally similar to IIystris, but without a crest or mane and quills not so long. Cranially it differs in having much smaller nasals, extending back only as far as on a level with the lachrymal bones, and contained into the dorsal outline two and onehalf times, instead of extending as far back as the squamosal roots of the zygomata and contained into the dorsal outline one and one-half times, as in IIystrix. No depression on upper surface of skull at the union of sagittal and coronal sutures. Molars rootless.

Fixternal characters.-Size large; head and body about 600 to 700 mm . ; tail short, about one-fifth length of head and body. Upper surface of head clothed with stiff, rounded, bristly hairs, those on the nape considerably elongated, but not forming the well-defined mane or crest found in Mystrix. Upper half of back and shoulders covered with flattened spines, usually each with dorsal and sometimes ventral grooves. Ahout the middle of the back these spines replaced by large heary quills, light in color, with a single dark band near the middle or toward the basal side of the middle. The quills vary in length from 50 to 2.50 mm , and are longest toward the middle of the back, becoming quite short near the rump, where, however, they are still quills and bear no resemblance to the Hattened spines found on the upper half of the back. On the base of the tail the quills become longer again. The distal portion of the tail is clothed with peculiar hairs. (Plate LVII, fig. 1.) The basal portion of each ( 10 to 1.5 mm .) is quite hair-like, but it abruptly expands out into a hollow cylinder, like an elongated capsule, about 5 mm. wide and about four to tive times as long. Nearly always the ends of these capsule-like hairs are open, but rarely the sides of the capsule are prolonged to meet in a
pointed aper. The sides of head, the under parts, and the legs are in general corered with soft flattened spines similar to those in the npper back. but shorter and not so stiff.

Skeleton. -The main featrres of the skull of the gems Acanthion have previously been pointed out. The relative size and shape of the skull and of its rarious parts are clearly shown in fig. 5, Plates LIV, LY, and LVI, so that no detailed deseription is necessary here. The vertebral formula is Cv. 7, D. 14, L. 5, S. 4 , Cd. abont 15. The axis bears a large rectangular nemal spine, projecting backward as a thin plate of bone, laterally compressed. (Plate LVII, fig. 11.) The seventh cervical hears a long pointed neural spine, about three times the length of the neural spine in front of it, and about half the size of the first dorsal spine. The lumbar vertebree have large rectangular lateral processes, directed forward. (Plate LVII, fig. 12.) The first and half of the second sacral vertebre serve for the attachment of the ilia. The presternum is relatively long, and its expanded part relatively narrow. The limb bones are relatively short and heavy, the seapula wide.

## ACANTHION BRACHYURUM (Linnæus).

> 1758. [Ifystrix] brachyura Linneus, Systema Naturee, I, 10th ed., p. 57. Based on Sebs, Rerum Nat. Thesaur., I, p. 81, pl. lit, fig. 1, from Java, Sumatra, and from Malacca. In view of Sela's name Mystrix maluccensis and his especial reference to its locality as Malacea, that country may properly be considered the type-locality.
> 1866. Actutlucherus grotei (iray, Proc. Zool. Soc. London, 1866, p. 310, pl. xxxi.
> Type-locality: Malacca. (See Proc. Zool. Soc. London, 1866, p. 417.)
> 1871. Hystrix longicaula, Sclater, Proc. Zool. Soe. London, 1871, p. 234.
> 1900. Hystrix longicauda, Flower, Proc. Zool. Soc. London, 1900, p. 364.
> 1903. Hystri. grotei, Bonhote, Fasc. Malay. Zool., I, July, 1903, I. 39, pl. in.

Distribution.-Malay Peninsula.
Diagnostic characters.-Apparently the largest of the Malayan species. Greatest length of skull, 135 to 150 mm .

Color.-Upper half of back, top of head, underparts, and legs and feet, an indefinite blackish brown or brownish black; a dirty white or dirty buff patch on throat, partly extended upward and backward along the side of neck. This is followed by a blackish brown collar and this in turn by a lighter collar, but this latter is not always well marked. The quills are dirty white or dirty louft in color, each with a band of blackish brown 20 to 30 mm . wide at or below the middle.

Skull.-The only peculiarity of the skull of this species apparently is its large size, total length of an old adult being 1.50 mm . and of a young adult about 140 mm .

Measurement..--See table, page 593.
specimens examined.-One old femate from Champang, Tenasserim; two adults and two yomg from Trong, Lower Siam.

## ACANTHION LONGICAUDUM (Marsden).

1810. Hystrix longicande Marsuen, History of Sumatra, 3l ed., 1811, p. 118, name only, without description, anl pl. xirl $n$. l. with legend: "The Landak, IIystrix longicaude. Published by W. Marsden 1810." Type-locality: Sumatra.
1811. Hystrix mülleri Marshall, Proc. Zool. Soc. London, 1871, p. 235, footnote. Type-locality: "Padang-bessie (Sumatra)." See Jentink, notes Leyden Museum, I, 1879, p. 91.
1812. IIystrix mülleri Jextink, Notes Leyden Museum, I, 1879, 1. 89.
1813. Acanthion müllcri, Jentink, Cat. Syst. Mammifères, Mus. Hist. Nat. Paysbas, XII, p. 104.
1814. Hystrix lomgicauda, $W_{\text {illine, }}$ Natuurkundig Tijdschrift NederlandschIndië, LXV, p. 265.
1815. Hystrix longicauda, Schneider, Zool. Jahrb., Syst. Geogr. Biol., XXIIII, p. 113.

Distribution.-Sumatra.
Diagrostic charactors.-Similar to Acanthion brachyurum, but apparently slightly smaller; with less conspicuous throat collars.

Color.-As in A. brachyumam, but in the single available specimen the light throat collar very poorly defined and the sides of body are lighter in color, owing to the spines having lighter bases than in A. brachyurum.

Skull.-Evidently smaller than that of A. Drachyurum. Jentink ${ }^{a}$ gives the total length of the skull of an old male as 135 mm . The skull of a young male in thie U. S. National Museum measures 103 mm . total length, against 110 mm . total length in a skull of the same age, as judged by the teeth, firom the Malay Peninsula.

Measurements.-Sce table. page 593.
Specimens examined.-One, a young male, from Aru Bay, Sumatra.
Remarks.-Jentink ${ }^{b}$ records Acanthion mülleri and I Icanthion jaianicum from Sumatra, Tanjong Morawa. No description of them is given, but it is to be supposed that they differ, as pointed out by Jentink ${ }^{*}$ in 1879 , mainly in size-in which case there are two distinct forms of Acanthion in Sumatra. That Jentink did not have a specimen of Thecurur, is evident from the fact that the smaller of his species, A. jaranicum, has a skull length of 118 mm ., while the skull length of Thecurus is scarcely more than 100 mm .

## ACANTHION JAVANICUM F. Cuvier.

1822. A [canthion] jaranicum F. Cuvier, Mem. Mus. Hist. Nat. Paris, IX, 1822, p. 431, pl. xx bis, figs. 3.4. Type-locality: Java.
1823. Hystrix torquatu van der Hoeven and de Vriese, Tijdscrift Natuur. Geschied. en Physiol., I1I, 1836, p. 110.
1824. II[ystrix $]$ brerispinosa Wagner, Supplementhand Schrebers Sïugthiere, IN, p. 20.
[^2]```
1839-64. II[ystrix] juranicum, Blanvible, Oitegg. Mamm., I \, pl. it.
1848. Hy.stri. jovanica, Waterhocse, Nat. Hist. Mamm., II, p. 4fiñ, pl. xx,
    fig. 4.
1854. Actuthion juranicum, Gervals, Mist. Nat. Mamm., 1. S32.
1866. Acanthion jawanicum, Gray, Proc. Zool. Soc. London, 1866, p. }310
1871. Ihystrix jucumicu, Marshall, Proc. Zool. Soc. London, 1871, p. 235, foot-
    note.
1879. I|[ystrir] jarunicu, Jextink, Notes Leyden Museum, I, 1879, pp. 87, 88.

    Pays-laas, NII, p. }103
1905. Ilystrix jacanica, Wılink, Natuurkundig Nederlandsch-Indië, LNT. p.
    266.
```

Distribution.-Java.

Remathw. I have seen no specimens of this species. There is a skeleton of an old individual in the National Museum, labeled " IIystrin jucunica: Java." It was purehased from a dealer several jears ago, and probably labeled "Java" becatse it had been identified as Hystrix jacunica. The total length of the skull measures 135 mm . It is distinctly smaller than skulls of like age from the Malay Peninsula, but at the same time mueh larger than the 118 mm . given by Jentink" as the total length of a Javan Acunthiom skull.

## ACANTHION CRASSISPINIS (Günther).

1876. Iystrix crassispinis Güntmer, Proc. Zonl. Sue. London, 1876, p. 736, fig. 1, p. 737; fig. 1a, p. 738; pl. LXX.
1877. Itystrix crassispinis, IIose, Mammals of Bornen, p. 60.
1878. Iystric crassispinis, Whlank, Natuurkundig Tijdschrift Nederlandsch; Indië, LXV, 1. 266.
Distribution.-Borneo.
Diagnostic characters.-Size small; skull, total length 110 mm . Spines thick, equal twice the diameter of an incisor, longitudinally grooved on their upper surfaces.

Remarlis.-I hare seen no specimens of this speeies, but Günther's original description shows that it is a well-marked form. His plate woukd indicate that it is a lighter (browner) eolored animal than either Acanthion brachyumum or longicaudum. His measurements show it to be a smaller animal than A. jaranicum.

In Mammals of Borneo, ${ }^{b}$ Hose records Mystrix mülleri Jentink, also from Bormeo, saying: "This porcupine is like Mystrin" crussispimis, but distinguished from it by its back belly and somewhat different caudal quills. The skull also differs, but the size of the animals are much the same." In all probability A. crassispinis has a dark belly, although there is nothing in the original description to show that the belly is light or dark. It is thus impossible to say how Hose's seeond species of short-tailed poreupines from Borneo differs from Acunthion
crussispinis. It is possible that two or more species of the genus Accuthion are found on Borneo; but at present there is nothing in the literature to show this fact satisfactorily or to indicate what their characters are.

THECURUS, new genus.
Fimily.-Hystricidx, subfamily Hystricina.
Type- Thecurus sumutra, new species. (Description on page 58\%.)
speciex.-The type species is the only known one in the genus so far as known.

Hiugnostic chupacters.- Externally like a small Acanthion, but cap-sule-like ends of caudal hairs, smaller and relatively shorter, often closed at the ends (Plate LVII, fig. 2), quills smaller, and replaced on lower rump by grooved spines similar to those on upper back. Cranially very similar to the genus Atherurus, but brain-case relatively wider, rostrum narrower, and no well-marked fossa on outer side of mandible just beneath condylo-coronoid notch: molars rootless.

Esternal characters.-About half the size of Acanthiom, to which it has a striking resemblance, but it has no bristly hairs on the head or neck, hut merely soft, flattened spines. The flattened spines extend farther down the back than they do in Acanthion and are more conspicnously grooved, and they are also found on the lower back and rump instead of the short quills of Acantlion. The large heary quills occupy abont the third fourth of the back. They are much less numerous and shorter than those of Acanthion, the largest not exceeding 150 mm . These quills are dark in color, with a light base and apex. A very few long stiff bristles are interspersed among the quills. Some short quills are found on the base of the tail, while the terminal portion of that organ is covered with peeuliar modified hairs, but the capsules are relatively much shorter and a great many more of them are cloved at the apex-drawn out to a point. (Plate LVII, fig. थ.) The sides of the head, the underparts, and the legs, are in general clothed with rather soft, flattened, grooved spines.

Skeleton.-The main features of the skull of the genus Thecurus have previously been pointed out. The relative size and shape of the skull and its various parts are clearly shown in fig. 1. Plates LIV, LV, and LVI, so that no detailed description is here necessary. The vertebrail formula is: Cr. 7, D. 14, L. 5, S. 4, Cd. 17. Although the skeleton of Thecurus as a whole, aside from the skull. is in general strikingly like that of Acenthion, yet in one or two points it is quite different. Instead of having it large, laterally compressed neural spine on the axis, that vertehra bears a relatively short, tri-prismatic spine, not compressed laterally any more than it is antero-posteriorly. (Plate LVII, fig. 9.) The seventh cervical vertebra in Themers has no long neural spine. The long neural spine on the seventh cervical seen in Acan-
thion has been shifted backward in Thecums and is found on the first dorsal vertebra; the very long neural spine on the first dorsal of Acanthion occurs on the second dorsal in Thecurus. The lumbar vertebrae (Plate LVII, tig. 10) in Thecurns have large rectangular lateral processes, directed anteriorly much as in Acauthiom, but the processes are rather more slender. 'The first and one-half of the secont sacral vertebre serve for the attachment of the ilia. The presterntm is relatively shorter in Thecuros than in Acanthion and the expanded part is relatively wider. The limb bones are relatively short and heary, proportioned as they are in Acanthion, but the anteriorly projecting "knee" at about the middle of the tibia is more pronounced. The scapula is somewhat wider, in proportion to size, in Thecurus than in Acenthion. It is almost identical in size and shape to the seapula of Athermeras.

## THECURUS SUMATRÆ, new species.

Type.-Skin and skull of adult mate, Cat. No. 14:342, U.S.N.M., collected at Aru Bay, east coast of Sumatra, Jamary 17, 1906, by Dr. W. L. Abbott. Original No. 4637.

Distribution. - Known only from the vicinity of Aru Bay, Sumatra.
Diagnostic characters. - The same as given for the genns above.
Color.-General color on top of head and anterior half of back, much like a dark drab of Ridgway, specked, especially on top of neck and toward the sides with the dirty white tips of the spines. Sides of head and neek and underparts drab. conspicuonsly specked with the dirty white tips of the spines. Under side of neck dirty white or cream-butf, erossed by a drab collar 25 to 30 mm . wide. The feet and legs are darkened almost to Kidgway's seal brown. The quills are blackish, with dirty whitish tips of 20 to 25 mm . Apines on the lower back blackish with short (abont 5 mm .) light-colored tips.

Shull and teeth.-The characters of the skull have already been described. The skulls as a whole show a great deal of individual variation in respect to size, comparative width of skull, and length of nasals. (See table of measurements, p. 593.) The teeth show equal rariation in size, No. 143434 having the length of upper toothrow 19.5 mm . and No. 143435 , with teeth worn to the same extent, 17.2 mm. Wear produces rery striking effects on the teeth; reentrant angles seen in the young and in the young adults are entirely lost in old iudividuals, and judging by the teeth alone one might easily consider roung and aged adults to belong to different genera.

Meastiomentr.- External measurements. (See table, p. 593.) Cranial measurements of the type: Basal length, 92.3 mm ; basilar length, 85; condylo-hisal length, 99.t; greatest length, 108; upper length, 103.7; palatal length, 51.3 ; zygomatic breadth, 56 ; distance between outer margins of extermal anditory meatns, 42.8 ; interorbital constric-
tion, 31.8; greatest length of nasal, 29.6; width of both nasals together, 15; maxillary toothrow (alveoli), 19.3; mandibular toothrow (alreoli), 19.5.

Specimens examined.-Nine skins with skulls, one odd skull, and one skeleton, all from Aru Bay, east coast of Sumatra.

Remurlis.-Thecupus sumatre is a very distinct form of poreupine and apparently bears little resemblance to other described genera or species. Externally it closely resembles a small Acanthiom, while cranially it has so many points in common with Atherurus that there are almost no characters, aside from rootless molars, by which the two may be generically separated. In many respects it is an intermediate link between icanthion and Athernme.

In $1879^{a}$ Doctor Gunther described a small porcupine from the island of Paragua, Philippine Islands, under the mame of Mystrix pumila. I have seen no specimens of this species nor any figures of it, but the original description and the detailed measurements given lead me to believe that Mystrin pumila is closely related to Thecurus sumatrie and may possibly be a second species of that genus. Whatever the relationship, Doctor Günther's measurements indicate that Mystrier pumila is a distinetly smaller animal than Thecurus sumatre.
Subfamily A'rHERURINAE.

The subfamily Atherurine is distinguished among the Hytricida in the possession of a rather long external tail, with a well-marked scaly portion between its base and apex, which is terminated by a long tuft of modified hairs or bristles; in not having well-developed quills on the back, but merely stiff grooved spines; in having three sacral vertebrie and rooted, brachydont molars. It contains two genera: Atherurus, page 58t, and Trichys, page 5ss.

## ATHERURUS F. Cuvier.

1829. Atherurus F. Cuvier, Dict. Sci. Nat., LIX, p. 483.

## Tippe-Mystrix macroure Linnwus, from Malacca. ${ }^{b}$

Species.-(In Malayan region) Atherurus macoumus (Limnæus), from Malacea; A. zygomaticus Miller, from Pulo Aor; and A. teruture, new (page 587) P'ulo Terutau.

Diagmostic characters.-A small sized poreupine, without quills, with a large scaly tail, each scale subtended by three hairs, and terminated by a tuft of bristles, mostly flattened and altermately contracted and expanded one to five times. (Plate LVII, fig. 3.) Skull

[^3]in many respects like that of Thechrns, but relatively marrower and with less abrupt rostrum, and with a well marked fossa on side of mandible beneath the condylo-coronoid notch and with rooted molars. Differs from the skull of Trichys. in the absence of postorbital processes, and in having distinctly heavier malars.

Ertemal charecters.-Size small, a little less that of Thecurns, tail long, about one third head and body. Entire upper parts and sides of body and base of tail corered with heary, somewhat thattened spines, with a large groove on their dorsal aspect, and a shallow groove on their underside at the hase. The spines are fongest on the lower back, rump, and base of tail where they are about 75 mm . long. No quills proper are found on this pormpine, but interspersed among the flattened, groored spines on the lower hack are a few rounded stiff loristles, somewhat quill-like at the base, having a length of 100 to 125 mm . The head, underparts, and the legs, are rlothed with soft, flat spines. The basal fourth of the tail is covered with spines, like those of the lower back; the middle two-fourths are covered with scales, each of which is subtended by three short hairs, a median stiff, long one, with a shorter finer one on either side; the terminal fourth of the tail is mainly corered with peculiar flattened hollow hairs and some ordinary bristles. Each of these peculiar hairs begins with a hair-like base, hut soon expands into a small. narrow, hollow, flattened capsule, followed by a short hair-like space and then another flat, hollow capsule, some hairs having as many as five such expansions. These hairs always terminate in an expansion with a long drawn-ont apex. (Plate L'II, fig. 3.)

Skeleton.-The main features of the skull of the genus Athermps have previously been pointed out. The relative size and shape of the skull and of its various parts are clearly shown in fig. 2, Plates LIV, LV, and LVI, so that no detailed description is here necessary. The vertebral formula is Cv. 7, D. 14, L. 5, S. 3, Cd. 24. The axis hears a large neural spine flattened from side to side, similar to that found in Aconthiom, but subtriangular in ontline and directed backward at a sharper angle. (Plate LVII, fig. 7.) The serenth cervical hat a short neural spine, like that of the sixth, and the long spine of the serenth seen in Acanthion has been shifted batkward to the first dorsal, as in Thecuras. The lumbar vertebra have rather narrow lateral processes, directed forward at a more acute angle than they are in the two preceding genera, and the ends of the processes are some what eularged. (Plate LVII, fig. 8.) Only three vertebre compose the sacrum in Atherurus, and the first alone serves for the attachment of the ilia. The prestermm is relatively short, and its expanded portion relatively narrow. The humerus is relatively more slender in Ithermus than it is in Acenthion or Thecurus; the deltoid ridge is less promi-
nent, and the olecranon process of the ulna is shorter. The femur, tibia, and fibula are proportioned about as they are in the two preceding genera, but the metatarsals and phalanges are relatively longer. The scapula of Atherurus is broad.

## ATHERURUS MACROURUS (Linnæus).

1758. [Hystrix] macroura Linneu's, Systema Nature, 10th ed., I, p. 57. Based on Seba, Rerum Nat. Thesaur, I, p. 84, pl. bin, fig. 1. Locality not known, other than East Indies. ${ }^{a}$
1759. Hystrix mucroure, Shaw, Gen. Zool., II, Pt. 1, p. 9, pl. cxxiv.
1760. Ithertura fusciculatu, Bennett, Gardens and Menagerie Zool. Soc. London, pp. 175-178.
1839-64. II [ystrix] fasciculata, Blanville, Osteog. Mamm., IV, pl. if.
1761. II[ystrix] fasciculatu, Wager, Supplementhand Schrehers Siugthiere, IV, p. 23.
1762. Hystrix mucroura, WAGNER, Supplementband Schrebers Säugthiere, IV, pl. clex.
1763. Atherura mucroura, Wateriouse, Nat. Hist. Mamm., II, p. 472.
1764. Atherurus fuscimulut, Gervais, Hist. Nat. Namm., p. 333.
1765. A[theruru] mucroura, Günther, Proc. Zool. Soc. London, 1876, p. 742, fig. 3.
1766. $H$ [!/strix] macrouru, Jentink, Notes, Leyden Museum, I, 1879, p. 87.
1767. Atherura maerura, Blanfori, Fauna British India, Mamm., p. 446.
1768. [Atherura] macroura, Jentink, Notes, Leyden Museum, X VI, I894, p. 207.
1769. Atherura macroura, Willink, Natuurkundig Tijdschrift Nederlandsch Indië, LXV, p. 267.
Distribution.-Malay Peninsula, Burma, and perhaps various Malayan Islands.

Color.-Gencral effect of top of head, upper back, and of feet, Ridgway's drab, rather dark. The heavier spines are a blackish brown. On the sides, thighs, and underparts the spines have dull. dirty whitish hases and subterminal apical bands, with a drab or drabgray band between them, and a very slight drab-gray apex. The chin and upper throat are particularly light, as well as an ill-defined band across the chest. The light color of the bases and of the subterminal rings of the spines show to a marked extent on the sides and underparts. The tuft of bristles at end of tail vary from dirty whitish to a dirty cream buff.

Meusurements. -See table, page 593.
Specimens extmined.-Four, from 'Trong', Lower Siam.
a Seba's figure shows an animal much less spiny than any Malayan specimens I have seen. The lescription of the tail does not agree with specimens of this genus in the U.S. National Museum. Seba likens the swelling on the caudal bristles to grains of rice inclosed in an envelope. In the specimen at hand each bristle, while hollow, is flat and alternately widened and contracted laterally in one plane only, and the expansions are much longer than are the enlargements shown in Seba's figure. It is barely possible that the animal usually designated as Atherurus mucrourus (Linneus) is really an undescribed species. At least it would so appear if Seba's account is at all accurate.

## ATHERURUS ZYGOMATICUS Miller.

1903. Atherura zygmutica Miller, Smithsonian Miscell. Coll., XLV, November 6, 1903, p. 42, pl. ı, fig. 4. Type-locality: Pulo Aor, off roast of Johore.

Distribution.-Known only from Pulo Aor, ofll coast of Johore.
Type.-Adnlt female, skin and skull, Cat. No. 11ə429, U.S.N.M., collected on Pulo Aor, otf coast of Johore, June f, 1901, by Dr. W. L. Abbott, Original No. 1009.

Diagmostic charucters.-Like Athermrus meecomemes, but color darker, and zygoma shorter and deeper, under side of malar hone with a conspicnous tooth-like process directed backward. hachrymal bone much smaller, scarcely appearing on dorsal aspect of skull.

Color.--Very similar to that of Athermme mencommes, but slighty darker, especially along the sides, due to the light area of the spines being less in evidence.

S/aull and teeth.-In general, the skall is very similar to that of Athermpus mucrourms of the Malay Peninsula, but in size it is somewhat smaller and differs conspicuously in regard to the lachrymal bones and the zygomata.

In Atherura macroura the lachrymal is fully 8 mm . in length below the rim of the orlit, while above it extends forward as a triangle of bone at least 5 mm . long, and is a noticeable feature of the dorsal aspect of the skull. In A. zygomution its length below rim of orhit is usually about 5 mm ., * * * while the forward extension is often obsolete and never large enomgh to le more than barely visible when the skull is viewed from above. Zygoma shorter than in Itherura murroure, the jugal deeper in proporton to its length, more abruptly concaved above, and its lower contour invariably * * * broken by a strongly developed concavity bemeath posterior jugal suture, this concavity terminating anteriorly on the posterior upper surface of a well-markel tooth-like projection. "

Measurementr.-For a comparison of the cranial measurements of the type, with the type of Itherurus temones and with an adult female from Trong, Lower siam, see page 588. For measurements of the serifs, see table, page 593.

Specimens extmimed.-Seven; all from Pnlo Aor.

## ATHERURUS TERUTAUS, new species.

T!/pe.-Skin and skull of adult male, C'at. No. 123971. U.S.N.M., collected on Pulo Terutau (also written Trotau and Trotto), about 15 geographicalmiles west of the Maray Peninsula, where the one hundredth meridian east of Greenwich cuts the west coast of the Malay Peninsula, April 10, 1904, by Dr. Wr. L. Abhott. Original No. 3223.

Dingmostic cherrectes. Like Athemurns mueromrns of the Malay Peninsula, but smaller, with shorter tail; lachrymal bone much smaller, scarcely appearing on the dorsal aspect of the skull. It

[^4]resembles A. aygometions from Pulo Aor in its suall lachrymal, but lacks the heary zygoma and the step-like projection on its inferior border. Caudal bristles shorter than in either A. macronrus or 1. aygomutious, and with the single (in the other species these are usually three to five on a bristle) expansion relatively narrower and longer. The bristles, however, have a worn appearance, which might account for this difference.

Color.-The color of Atherurus terutaus so closely resembles that of A. syyomaticus that no detailed description is necessary.

Shull and teeth. - In general, similar to those of Atherurus macrourus, but distiuctly smaller, rostrum and masals relatively shorter, constriction between the orbits more pronounced, depression on top of skull greater; lachrymal bone much smaller, scarcely any of it appearing on the dorsal aspect of the skull; in this respect resembling the skull of A. zygomaticus; zygomata of the same form as in A. macromins; audital bulle, smaller. Teeth of same form as in A. macrourus, but smaller.

Meusurements.-See table, page 593. Cranial measurements of the type: Greatest length, $93.2 \mathrm{~mm} .(94.3,99) ;^{a}$ basal length, 82.2 ( 82.6 , 87.4); basilar length, 76.1 ( $75.6,80.5$ ); condylo-basal length, 87.8 ( 89 , (94.2): palatal length, 44.7 ( $45.5,47.6$ ); greatest length of nasal, 22 ( $25.3,26.3$ ); zygomatic breadth, 45.8 ( $45.3,47.5$ ); least interorbital breadth. 24.5 (26.1, 28.4); maxilary toothrow (alveoli), 15.7 (17.1, 17.2); mandibular toothrow (alveoli), 17.3 (17.9, 18.8).

Specimens cxamined.-One, the type.
Remarlis.-Althongh but one specimen of Atherurus terutaus is known, its peculiarities are so well marked that its specific distinctness from A. macrourus and A. zygomaticus can not he doubted. It possesses the peculiar lachrymal bones of A. zygomuticus, but its zygomata are exactly as they are in $A$. macrourus from the mainland.

## TRICHYS Günther.

1876. Trichys Günther, Proc. Zool. Soc. London, 1876, p. 739, fig. 2; p. 740, fig. $\ddot{P}^{2}$, p. 741 and pl. Lxxi.
Type. - Trichys lipure, from Borneo.
Species. - Trichys. fusciculutu (Shaw), from Malacea: T. lipure Günther, from Borneo; T. mucrotis Miller, from Sumatra.

Diagnostic characters.-A small porcupine externally resembling Atherurus but with a relatively longer tail, each scale of which is subtended by a single hair and with the brushat end of tail composed of flat, grooved bristles, with parallel sides. (Plate LVII, fig. t.) Skull small, different from that of Athorurus in possessing distinct postorbital

[^5]processes，a more slender and pronounced rostrum，zygomata more converging anteriorly，and a heavy grooved malar of nearly uniform width throughout its length，which is subtended by a considerable hatekward extension of the maxillary portion of the zygoma．Molars rooted．

Hexryption of win．－Nize small，somewhat less than that of Athe－ mums，tail relatively longer．Upper parts and sides of body covered with spines more flat and less stiff than in Ithrmrms．groored both above and below，of about the same length（ 25 to 30 mm ．）all orer the back．Interspersed among them are a rery few stifl bristles，about 75 mm ．long．The head，underparts，and the legs are covered with softer，shorter bristles．＇The extreme base of the tail is covered with spines like those on the back．The greatest portion of the tail is covered with well－delined scales，each subtended by a single hair．Toward the tip the seales grow larger and the subtending hairs hecome longer（about 100 mm ．），flat，hollow bristles of uniform width thronghout their extent．（Plate LJII，fig．4．）

Slefetom．－The man features of the skull of the genus Trichys have previously been pointed out．The relative size and shape of the skull and of its various parts are elearly shown in fig．3．Plates LIV，LV， and LVI，so no detailed description is here necessary．The vertebral formula is：Cv．7，D．16，L．5，S．3．Cd．25．The axis bears a large laterally－compressed neural process，strongly curved and bent batck－ ward．（Plate LVII，fig．5．）The neural spine of the serenth cervical is short as it is in Thecumes and Atherums．The lateral processes of the lumbar vertebre are rather slender，curved，and directed forward， and with a somewhat pointed apex．（Plate LVll，fig．6．）The sacrum is of form similar to that of a themoms：it contains three vertebrat，and to the first of these the ilia are attached．The prestermum is relatively short，and with a relatively narrow anterior expansion．The humerus and the bones of the forearm are proportioned as they are in the genus Atherums．The femur is relatively more slender in Trichys than in the other genera，and the metatarsals and phalanges are some－ what longer than they are in the genus $A$ therums．In Trichys the sapula is much narrower than in the other genera，and its anterior border is strongly rounded off．

## TRICHYS FASCICULATA（Shaw）．＂

1801．Mystrix fasciculutu，Shaw，（ien．Zool．，Il，l＇t．1，Mamm．，p．11，pl．（＇xxiv． Type－locality：Malacea．

    1900. Trichys lipure, Bonnote, Proc. Zool. Sore. London, 1900, p. 881.
```

    Distribution.-Malay Peninsula.
    Romarlis.-I have seen no specimens of this species which has min-
        ally been considered synonymons with the Bornean Trichys lipmra.
        Becanse of the general distinctness of mammals of the Malay Peninsula
        and those from Borneo, that view does not appear probable, and,
        hoth amimals having been manel, those names are here retained. It
        is possible, on the other hamd, that the Sumatran Trichys macrot is
        may be very close to the Malay Peninsula amimal.
            TRICHYS LIPURA Gunther.
            1876. Thichys lifurt Gitintner, Proc. 'hool. Soc. London, 1876, p. 739; fig. 2, p.

1905. Trichys fuscicmlata, W̌alink, Natuurkundig Tijdsehritt Nederlandsch-
Indië, LNv, ]. 207.
Distribution.-Borneo.

Calor.-- (teneral color above a sort of drab-brown. The bases of the spines are whitish, which is the general color of the underparts owing to absence of drab-brown tips of the spines. On the sides the color aradually passen from the almost complete (rab-hrown of the upper parts to the whitish of the belly.

Noull amb terth. -These are well figumed by Günthor. "and need no detailed description here.

Buffon's Porrapic de Malecta, I think he is in error in suying that the genus Trichys is mot known in Malaced, for it seems to have heen charly reorded from the Malay I'oninsula liy Bonhote (Iroc. Zool. Soc. London, 1!900, p. S81) and by Jontink (N゙otes
 Ilystrix mucromo Linnexs, the speries of Trimbys on the Xalay Peninsula (if it is distinet from the bornean amb smmatran amimats, as is probahle) has not yot received a valisl name. I lavmg seen no speemens of Trimbs from the Jalay Peninsula, I ran not venture to state whether it is distine from the two seecies alreaty named or with wheh one it thonld he asereiated. Aerordingly I have left the matter standing as originally written, but with this explanation.
a Proc. Zool. Soc. London, 1576, 121. 740 and 741.

Measurements. - See table, page 593.
Specimens ratmined. - Two, skin and skull of nearly adult male from Mount Salikan, Borneo, and the skeleton of an adult from British North Borneo.

## TRICHYS MACROTIS Miller.

1903. Trichys mncrotis Mhler, Proc: U. S. Nat. Mus., NXVI, p. 469, Fehruary 3, 1903. Type-locality: Tapanuli Bay, west coast of Sumatra.
1904. Trichys mucrotis, Wılınk, Natuurkundig Tijdschrift Nerlerlandsch-Indië, LX V, i. 268.
Distributiom.--Sumatra.
Type. Skin and skull of adult female, collected at Tapamuli Bay, west coast of sumatra. February 20 , 1:002, by Ir. W. I. Abbott. Original No. 1\%5\%.

Diemenstic churrectoms. Like Trichys liphere from Borneo, hut with tonger ears, more angled hamulars, and smatler lachermal bone.

Colni.- The color of Trichys. mencortis differs in no way from that of T. iipure.

Enns. - The ears in Trichys. mumpotix are much longer than they are in T. lipurn, and the tips broader and more romaded. Length of c:ar from meatus in the type of $T$. mumot is, 2e mm., in T. lipmon, Cat. No. S3940, from Borneo, is mm .

Shall. The skull clowely resembles that of Trimbys lipmin. Jut the hamular process of the pterygoid bone has a more pronomed bent or angle on its inferior aspect, and the tip, instead of ending in a point barely in contact with the andital halla, is considerahly thickened and generally in contact with the loulla. The lachrymal bone is apparently much longer in the Bomenn animal than in T'. morrotis, althongh in many specimens of the latter species the sutures are so obliterated as to render it impossible to determine its exact size. (ireatest length of the lathrymal bone in the two Bornean skulls, $s$ and 9 mm. respectively, in four Sumatran skills, 4 to 5.5 mm.

Mersurerementa.-See table page 593.
Specimens examimed.-Seven, a from Tapamuli Bay and $\unrhd$ from Aru Bay, Sumatra.
relationships of the four genela of malayan pordulanes.
The most primitive and umelated to the others of the Malayan porcupines is the gemus Tiridyg. Externally Trichys. and Atherimins are much alike, but the terminal tail bristles of Trichiss are peentiar and bear no distinct relation to those of Athormmer or to the other gemera. Both Trichys: and Atheruris have rooted molas, while the molars in the other two generatare rootless. Onteologically Tridhys shows many peculiarities not possessed ley the other gemera, sum as the generalized form of the skull, large number of dorsal vertebra and narrowed
scapula. Its skull and teeth show resemblances to those of Atherurus, and the sacra in the two genera are practically identical. Atherurus, although showing strong affinities to Trichys, appears in certain ways to be related to Thecurus. Nost of the skeleton of Atherurus is much like that of Thecurus, the only striking difference heing in the lessened number of sacral and caudal vertebre in Atherurus, and in the peculiar axis of Thecurus, which does not resemble in any way the axis of any of the other three genera. The caudal bristles of Athenurus might have been derived from those of Thecurus, or the reverse. If the candal bristles of Atherurus had but one enlargement, and that more inflated and less flattened, they would be of the type found in Theourus. Thecurns differs from any of the other three genera by its peculiar axis. Withont its skull and axis it could not be differentiated from Acanthion, while if only its skull were known there would be little excuse for separating it from Athormrus, provided no account were taken of its, rootlese molars. Accenthion is clearly closely related to /hystri, and less different from that gemes than it is from Thecurus, Atheremus, or Trichys. The five genera of OId World porcupines may be arranged serially thus:

Mystrix. * Acenthion * * Thecurus-Atherurus * * * * Trichys, with the most different genera at the extremes of the line and the most closely related next to one another. A break occurs between Thecurns and Atherurus so that two subfamilies may be recognized. Ihystrix and Acanthion are evidently directly and closely related to one another, and Thecuress is certainly much closer to them tham it is to the Atherurus-Trichys group. Whether Atherurus and Trichys are directly related to each other or are only distantly so related through a remote ancestry is difficult to say. The two subfamilies, Hystricine and Atherurine are scarcely of equal rank, the members of the former being much more homogeneous than those of the latter. Trichys, ${ }^{a}$ with its generalized structure is evidently the most primitive of the Hystricidæ and at the opposite end stands Hystrix. (Plates LIV, LV, and LVI, fig. 4), the most specialized, with its peculiar much modified skull and highly developed quills.

a Skeleton．
$b$ Estimated from skeleton．
$c$ Skin and skull．
$d$ Collector＇s measurements．
e Measured from skin．
$f$ Tail injured．
$g$ Skull only．
$h$ Last upper molars just coming into place．
$i$ Second upper molars just coming through alveoll．
$j$ Type．
$k$ Last molar not through alveolus．
$l$ Tail damaged．The loss of the external tail seems to be of rather common ocenrrenue among the long－tailed poreupines，and shows of how little practical use that organ is to them．
$m$ Estimated from mounted skin．

## EANLANATHN OF PLATES. <br> I'ates LIV, L', and ldi.

Lorsal, lateral, and rentral views of skulls of old World pormopines. All figures one-half matural size.

Fig. 1. Thecurus sumutric. Type, Cat. No. 143432, I.S.N.M., Aru Bay, Sumatra.
2. Ithernmes torutaus. Type, Cat. No. 123971 V.S.N. M., Palo Torutan, west coast Malay I'eninsula.
3. Trichys murrotis. Type, Cat. No. 114438 , U.S.N.M., Tapanuli Bay, Sumatra.
4. Inystris oristata. ('at. No. $\frac{49348}{60048}$, U.S.N.M., received from National Koological l'ark.
5. Ictuthion brachyntum. ('at. No. S3519, U.S.N.M., Trong, Lower Siam.

Plate livil.
Tail hristles and eervical and lumbar vertebre of Malatyan [orcupines. All figures three-fourths natural size.

Fig. 1. Tail bristle of Arenthion.
$\because$ Tail bristles of Thecurns.
3. 'Tail bristle of 1 therotus.
4. Tail bristle of Trichys.
5. Axis or secome cervical vertelma of Trichys.
6. Limbar vertelora of Trich!!s.
7. Axis or second cervical vertebra of 1 thormas.
8. Lumbar vertebra of Ithermats.
9. Ixis or second cervical vertebra of Thathres.
10. Lumbar vertehra of Theromes.
11. Axis or second cervical vertetnat of Icauthion.
12. Lumbar vertebra of Icunthion.
